57 **Disclosure statement:** The authors report no conflict of interest. We note that Dr. Alisa
58 Kachikis has received honoraria for work on maternal immunization through Pfizer and
59 GlaxoSmithKline, which are outside the scope of this manuscript.

60 **Source of financial support:** This work was primarily supported by funding from the
61 University of Washington Department of Obstetrics & Gynecology and Gift Funds. This
62 work was also supported by the National Institute of Allergy and Infectious Diseases
63 (grant numbers AI133976, AI145890, AI144938 and AI143265 to KAW and AI120793 to
64 SML). Study data were managed using a REDCap electronic data capture tool hosted by
65 the Institute of Translational Health Sciences at the University of Washington, which was
66 supported by the National Center for Advancing Translational Sciences (UL1TR002319).
67 The content is solely the responsibility of the authors and does not necessarily represent
68 the official views of the National Institutes of Health or other funders.

69 **Role of the funding source:** The funders had no role in study design, data collection
70 and analysis, decision to publish, or preparation of the manuscript.

71 This manuscript has not been presented at a meeting.

77 Word count (main text): 3,226

78

79 **Condensation:**

80 In this Washington State case series, severe Covid-19 occurred in 15% of pregnant
81 patients, who were typically overweight or obese pre-pregnancy or had underlying
82 conditions.

83

84 **Short Title:**

85 Covid-19 in Pregnant Women in Washington State

86

87 **AJOG at a Glance:**

88 A. Why was the study conducted? The study was performed to determine the impact
89 of Covid-19 on the health of pregnant women in Washington State.

90 B. What are the key findings? In this case series of 46 pregnant individuals with a
91 laboratory-confirmed SARS-CoV-2 infection, nearly 15% developed severe Covid-
92 19, which occurred primarily in overweight or obese women with underlying
93 conditions.

94 C. What does this study add to what is already known? Collectively, these findings
95 support categorizing pregnant patients as a higher risk group, particularly for those
96 with obesity and chronic co-morbidities.

97

98 Keywords: asthma, coronavirus, Covid-19, fetal death, infection, maternal morbidity,
99 obesity, overweight, pregnancy, SARS-CoV-2, preterm birth, respiratory insufficiency,
100 stillbirth

101

102 **ABSTRACT**

103 **Background:** The impact of the coronavirus disease 2019 (Covid-19) on pregnant
104 women is incompletely understood, but early data from case series suggest a variable
105 course of illness from asymptomatic or mild disease to maternal death. It is unclear
106 whether pregnant women manifest enhanced disease similar to influenza viral infection
107 or whether specific risk factors might predispose to severe disease.

108 **Objective:** To describe maternal disease and obstetrical outcomes associated with
109 Covid-19 disease in pregnancy to rapidly inform clinical care.

110 **Study Design:** Retrospective study of pregnant patients with a laboratory-confirmed
111 severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) infection from six
112 hospital systems in Washington State between January 21, 2020 and April 17, 2020.
113 Demographics, medical and obstetric history, and Covid-19 encounter data were
114 abstracted from medical records.

115 **Results:** A total of 46 pregnant patients with a SARS-CoV-2 infection were identified from
116 hospital systems capturing 40% of births in Washington State. Nearly all pregnant
117 individuals with a SARS-CoV-2 infection were symptomatic (93.5%, n=43) and the
118 majority were in their second or third trimester (43.5%, n=20 and 50.0%, n=23,
119 respectively). Symptoms resolved in a median of 24 days (interquartile range 13-37).
120 Seven women were hospitalized (16%) including one admitted to the intensive care unit.
121 Six cases (15%) were categorized as severe Covid-19 disease with nearly all patients
122 being either overweight or obese prior to pregnancy, asthma or other co-morbidities. Eight
123 deliveries occurred during the study period, including a preterm birth at 33 weeks to

124 improve pulmonary status in a woman with Class III obesity. One stillbirth occurred of
125 unknown etiology.

126 **Conclusions:** Nearly 15% of pregnant patients developed severe Covid-19, which
127 occurred primarily in overweight or obese women with underlying conditions. Obesity and
128 Covid-19 may synergistically increase risk for a medically-indicated preterm birth to
129 improve maternal pulmonary status in late pregnancy. Collectively, these findings support
130 categorizing pregnant patients as a higher risk group, particularly for those with chronic
131 co-morbidities.

132 INTRODUCTION

133 The coronavirus disease of 2019 (Covid-19) has led to the largest and deadliest pandemic
134 since the 1918 influenza pandemic. The first reported case of Covid-19 in the United
135 States was in Washington State on January 21, 2020; the United States now has the
136 highest rates of Covid-19 prevalence and mortality worldwide(1, 2). Covid-19 is caused
137 by the severe acute respiratory distress syndrome coronavirus 2 (SARS-CoV-2), which
138 results in a spectrum of disease ranging from asymptomatic and mild cases to respiratory
139 failure, shock, multiorgan dysfunction and death(3).

140

141 The clinical course of Covid-19 in pregnant women is incompletely understood and there
142 is concern for enhanced disease in some pregnant women and an increased risk for
143 spontaneous abortion, preterm birth or morbidity/mortality in the fetus and neonate(4-8).
144 Several case series have reported a variable course of illness in the antepartum,
145 intrapartum, and postpartum periods(9-14). Limited reports suggesting vertical
146 transmission underscore the potential vulnerability of the fetus and neonate(15-18).
147 Further, the relationship between timing of infection in pregnancy and the long-term
148 impacts on neurodevelopmental and neuropsychiatric outcomes in the children are
149 unknown(19, 20). Many questions remain unanswered, including whether pregnancy is a
150 high-risk state for enhanced disease in some circumstances and the impact of infection
151 on the developing fetus and neonate.

152

153 Washington State has been on the forefront of the national Covid-19 response. It was
154 among the first states to confirm community transmission(21) and to declare a State of

155 Emergency(22). In response to the pandemic, the Washington State Covid-19 in
156 Pregnancy Collaborative was established to investigate cases among pregnant patients
157 at major tertiary referral centers and community hospitals disproportionately impacted by
158 the pandemic. The study objective was to describe maternal and obstetrical outcomes
159 associated with Covid-19 disease in pregnancy to rapidly inform clinical care.

160

161 **MATERIALS AND METHODS**

162

163 **Study Design & Study Population**

164 We identified pregnant women (≥ 18 years) with laboratory-confirmed SARS-CoV-2
165 infections from six hospital systems in Washington State between January 21, 2020 and
166 April 17, 2020. All pregnant patients with a positive SARS-CoV-2 test result during any
167 trimester of pregnancy, regardless of symptoms, were included. All testing was performed
168 using a polymerase chain reaction (PCR) test, which varied in assay design and source
169 by institution. Participating institutions were part of the Washington State Covid-19 in
170 Pregnancy Collaborative, representing 16 hospitals from the Seattle-Tacoma-Bellevue
171 metropolitan area, Bellingham, Spokane and their surrounding areas. Sites included the
172 University of Washington Hospital system (Montlake, Northwest, and Harborview
173 campuses), Swedish Medical Center (First Hill, Ballard, Issaquah and Edmonds
174 campuses), University of Washington Valley Medical Center, MultiCare Health System
175 (Auburn Medical Center, Covington Medical Center, Tacoma General Hospital, Good
176 Samaritan Hospital, Valley Hospital and Deaconess Hospital), EvergreenHealth Medical
177 Center, and PeaceHealth-St. Joseph's Medical Center. These sites have 34,000

178 deliveries annually, which represent 40% of the ~86,000 deliveries each year in
179 Washington State(23).

180

181 **Patient Identification, Data Collection, and Statistical Analysis**

182 Eligible subjects were identified at collaborating institutions by site-specific team
183 members through electronic medical records searches using ICD10 diagnostic codes and
184 site-specific algorithms. De-identified data were abstracted from the electronic medical
185 records by a primary abstractor and entered into a REDCap database (Research
186 Electronic Data Capture software, Vanderbilt University) managed by the coordinating
187 team at the University of Washington. All data entry was confirmed by a secondary
188 abstractor. Abstractors included University of Washington School of Medicine students,
189 University of Washington Department of Obstetrics & Gynecology physician residents,
190 attending obstetricians, maternal-fetal medicine specialists and an obstetrical nurse. Data
191 collected included demographics, medical and obstetric history, SARS-CoV-2 testing and
192 clinical encounters including symptoms, laboratory results, pulmonary imaging and
193 hospitalization, when applicable. For patients who delivered by the time of chart
194 abstraction, we collected data on delivery characteristics and complications. Data were
195 summarized using proportions and medians (interquartile range, IQR). A Kaplan-Meier
196 curve was generated to estimate days from Covid-19 associated-respiratory symptom
197 onset to resolution. Patients with ongoing symptoms were censored at the last report of
198 symptoms in a clinical encounter.

199

200 **COVID-19 Disease Categories**

201 We used criteria for Covid-19 disease severity previously defined in non-pregnant
202 adults(24) and subsequently applied to pregnant women(25). Categories were defined
203 as: 1) mild (non-pneumonia or mild pneumonia), 2) severe (dyspnea, respiratory rate \geq 30
204 breaths/min, percutaneous oxygen saturation \leq 93% on room air at rest, arterial oxygen
205 tension over inspiratory oxygen fraction of less than 300 mmHg, and/or lung infiltrates
206 $>$ 50% within 24 to 48 hours, and 3) critical (severe respiratory distress, respiratory failure
207 requiring mechanical ventilation, shock, and/or multiple organ dysfunction or failure).
208 Normal laboratory reference ranges in each trimester of pregnancy are in Table S1(26).

209

210 **Placental and Fetal Histopathology**

211 In one case, a fetal autopsy was performed with gross and histopathological evaluation
212 of fetal tissues and the placenta. PCR testing of multiple fetal and placental tissues was
213 performed for SARS-CoV-2 RNA and cytomegalovirus DNA using established clinical
214 assays at the University of Washington.

215

216 **Ethics Statement**

217 This multi-site medical records review was approved by Institutional Review Boards (IRB)
218 at the University of Washington (STUDY# 00009701, approved 03/06/2020) and Swedish
219 Medical Center (STUDY #2020000172, approved 03/19/2020). All remaining sites
220 entered into reliance agreements with the University of Washington IRB for study
221 approval. Patient consent and HIPAA (Health Insurance Portability and Accountability
222 Act) authorization were waived by the IRBs for this study using de-identified data.

223 Consent to publish information associated with the fetal autopsy was obtained through a
224 study approved by the Seattle Children's Hospital IRB.

225

226 **RESULTS**

227 *Patient Demographics, Co-morbidities, & Pregnancy History*

228 A total of 46 pregnant patients with SARS-CoV-2 infections were identified during the
229 study period with a median age of 29 years (IQR 26-34) and 26.1% (n=12) were
230 nulliparous. One woman was pregnant with twins and the remainder had singleton
231 pregnancies. The majority were white (60.9%, n=28) and had private insurance (58.7%,
232 n=27). Positive SARS-CoV-2 test results were identified predominantly in second (43.5%,
233 n=20) and third trimester (50.0%, n=23) pregnancies; only three cases were detected in
234 first trimester pregnancies (6.5%; Figure 1). Approximately two-thirds of patients were
235 either overweight (28.6%, n=12) or obese (35.7%, n=15) by their pre-pregnancy body
236 mass index (BMI); two women met criteria for Class III Obesity (BMI ≥ 40). Although the
237 majority of patients were healthy, 26.1% (n=12) had an underlying health condition(s)
238 including type 2 diabetes (n=3), asthma (n=4), hypothyroidism (n=2), hypertension (n=2),
239 and several less common conditions (e.g. Crohn's treated with immunosuppressive
240 medication, seizure disorder history). Although no patients reported smoking cigarettes
241 during pregnancy, one reported marijuana use and one endorsed alcohol use.

242

243 *SARS-CoV-2 Testing & Symptoms*

244 SARS-CoV-2 testing became increasingly available over the study period starting with
245 facility-based and outpatient "drive through" testing stations for symptomatic individuals

246 and expanding to universal screening on Labor & Delivery at several medical centers.
247 Nearly all pregnant patients (93.5%, n=43) were tested due to Covid-19-related
248 symptoms (Table 2). The remaining three patients were asymptomatic but tested due to
249 known exposure. Women reported a median of two symptoms (IQR 1-5), which most
250 commonly included cough (69.8%, n=30), fever or chills (51.2%, n=22), nasal congestion
251 (48.8%, 21) and shortness of breath (44.2%, n=19; Table 2). Loss of taste or smell was
252 reported in 30.2% (n=13) of cases. Median time to symptom resolution was 24 days (IQR
253 13-37; Fig. 1 and Fig. S1). In one case, a woman with a prolonged symptomatic course
254 of at least 37 days, sought care in the emergency room three times and was hospitalized
255 once for respiratory symptoms. Follow-up data on symptoms were not available for three
256 women who were asymptomatic at SARS-CoV-2 testing. No co-infections were detected
257 in seven patients (15.2%) tested for other respiratory viruses (i.e. influenza and
258 respiratory syncytial viruses).

259

260 *Covid-19 Disease Course, Imaging, Medical Management and Hospital Admission*

261 The majority of cases were managed as outpatients for either mild in severity (78.3%,
262 36/46) or asymptomatic (6.5%, 3/46) presentations. Although few outpatients underwent
263 pulmonary imaging (12.8%, n=5/39), two women had pneumonia, but were not admitted.
264 An additional seven pregnant patients (15.2%) were hospitalized for Covid-19, one of
265 whom was admitted to the intensive care unit (Table 3). Six of the seven hospitalized
266 patients met criteria for severe Covid-19 disease (24). Nearly all patients with severe
267 disease were overweight or obese prior to pregnancy (80%, 4/5 with data) and half had
268 asthma and obesity-associated conditions (e.g. hypertension). Three (42.9%)

269 hospitalized patients received Covid-19-directed medications including
270 hydroxychloroquine and remdesivir (n=1) or remdesivir alone (n=2). Two patients
271 received azithromycin without concomitant hydroxychloroquine; one for possible
272 community acquired pneumonia and one in the setting of asthma exacerbation.

273

274 Laboratory testing was performed in 24 women, who were either hospitalized for Covid-
275 19 (n=7) or managed as an outpatient (n=17); due to multiple encounters, including
276 delivery admission, laboratory test results were evaluated from the time of Covid-19
277 diagnosis until delivery (Table 3, Table S2). Of the 24 patients with white blood cell
278 measurements, eight had leukopenia (33%) using pregnancy-specific laboratory
279 reference ranges ($<5.6 \times 10^3$ per μl ; Table S1); half of these patients (4/8) were managed
280 as outpatients. Neither creatinine nor C-reactive protein was elevated in those who had
281 testing (creatinine, 0/21; C-reactive protein, 0/6; Table S1). Seven patients had a mildly
282 elevated aspartate aminotransferase (AST), including five managed as outpatients
283 (31.3%, 5/16) and two that were hospitalized (33.3%, 2/6). Lastly, a markedly elevated D-
284 dimer was detected in one of five patients (20%) in which the test was ordered (Case 25:
285 4.08 ng/mL, Table 3).

286

287 The patient admitted to the intensive care unit was a young woman (20-25 years old) at
288 30 weeks, who presented with a one-week history of fever and cough. She was
289 overweight prior to pregnancy (BMI 26.2) and had asthma. She was admitted to the
290 intensive care unit due to acute respiratory failure with a percutaneous oxygen saturation
291 as low as 82% on room air and a respiratory rate as high as 49. She received remdesivir

292 (6 doses), hydroxychloroquine and high flow oxygen. She was transferred out of the
293 intensive care unit on day 3 and discharged home on day 6 (Table 3, Case 25).

294

295 *Maternal-Fetal Outcomes*

296 During the study period, 8 (17.4%) patients delivered, including seven live births and one
297 stillbirth (Table 4). The median number of days between a positive SARS-CoV-2 test and
298 delivery was 7.5 days (IQR 5.0-11.5). The median gestational age at delivery was 38.4
299 weeks (IQR 37.5-39.8). In one case, worsening respiratory status and multiple co-
300 morbidities, including Class III obesity, led to the decision to deliver the patient preterm
301 at 33 weeks gestation (Case 27, Table 3). Of the eight deliveries, five (62.5%) were
302 vaginal and 3 (37.5%) were cesarean delivery. Two of the three cesarean deliveries were
303 performed, in part, to improve maternal respiratory status due to Covid-19 disease. During
304 the delivery admission, two women developed postpartum preeclampsia with severe
305 features within one day of delivery; both women had elevated blood pressure, but no pre-
306 eclampsia-associated laboratory abnormalities. In these two cases, intravenous anti-
307 hypertensive medications were administered, but magnesium sulfate was not given due
308 to concern for exacerbating pulmonary edema.

309

310 Details of the case resulting in a stillbirth at 38.7 weeks are described in the Supplemental
311 Appendix. Postmortem examination of the placenta revealed severe chronic villitis, but
312 no viral inclusions. Qualitative PCR testing of placental and fetal tissues was negative for
313 SARS-CoV-2 and cytomegalovirus; notably, there was a delay between fetal demise and

314 RNA preservation for PCR analysis, which can lead to inaccurate PCR results. The
315 etiology in this case is unclear.

316

317 **COMMENT**

318 *Principal Findings*

319 This case series of 46 pregnant patients with Covid-19 represents all known cases across
320 six large hospital systems in Washington State from a time period when patients were
321 mainly tested based on symptoms. Notably, one in seven pregnant patients were
322 hospitalized for respiratory concerns and one in eight had severe Covid-19 disease.
323 Pregnant patients with severe Covid-19 were nearly all overweight or obese prior to
324 pregnancy and many had additional co-morbidities including asthma and hypertension.
325 Obesity as a risk factor for severe Covid-19 in pregnancy is particularly concerning as the
326 national prevalence of obesity was 39.7% among women of reproductive age (20–39
327 years old) in 2017-2018(27). Obesity is known to impair lung function through both
328 mechanical and inflammatory pathways(28). A synergistically detrimental impact on
329 maternal lung function may occur in the setting of multiple factors such as a Covid-19
330 pneumonia, obesity, asthma, and the added mechanical stress of an enlarged uterus in
331 late pregnancy; this combination may also increase the risk for a medically-indicated
332 preterm birth to improve maternal respiratory status.

333

334 *Results in the Context of What is Known*

335 Similar to the non-pregnant population, descriptions of the clinical course of Covid-19
336 disease in pregnancy have been variable (7, 17, 25). A systematic review of early case
337 series was notable for a low rate of admission to the intensive care unit (3%), no maternal

338 deaths, and only one neonatal death and one intrauterine fetal demise(6). In a recent and
339 larger case series from the Hubei province in China, the rate of severe pneumonia (7-8%)
340 in pregnant women was not higher than the general population (15%)(7). Newer reports
341 have highlighted critical cases in pregnant women involving respiratory failure,
342 mechanical ventilation, maternal death, as well as obstetrical complications like preterm
343 birth and intrauterine fetal demise(8, 17, 29-32). Our population-based case series of
344 pregnant patients with Covid-19 from counties in Washington State with the highest
345 burden of disease offers a unique insight into the disease course in pregnancy and
346 identifies potential risk factors associated with severe disease. Obesity, asthma and
347 hypertension appeared to be overrepresented in pregnant patients with severe disease
348 in our cohort, which is similar to studies in non-pregnant adults(33, 34).

349
350 *Clinical Implications*

351 Although outpatient management of Covid-19 may be safe for most pregnant patients,
352 the risks of Covid-19 for maternal health remains incompletely defined. There is evidence
353 of Covid-19-associated coagulopathy and whether pregnant women would benefit from
354 thromboprophylaxis is unknown(35). In our case series, the markedly elevated D-dimer
355 ($>4.0 \mu\text{g/ml}$) in a pregnant woman with severe Covid-19 is significant, because levels
356 greater than 1.0 and 2.0 $\mu\text{g/ml}$ have been linked to an increased risk for Covid-19-
357 associated mortality(36-38). Pregnant women are known to have an elevated D-dimer
358 during pregnancy, which may be as high as 3.3 $\mu\text{g/ml}$ in the second and third
359 trimesters(39) and could predispose pregnant women to an even greater risk for Covid-
360 19-associated thrombotic events and mortality. Laboratory testing of D-dimer should
361 be considered for pregnant women with Covid-19.

362

363 Pregnant women typically represent a unique and vulnerable group to infectious
364 diseases, not only because they often have enhanced disease (i.e. influenza and hepatitis
365 E viruses)(40), but also due to the detrimental impact on obstetrical course and neonatal
366 outcomes. In our series, the timing of delivery for one in four women was influenced by
367 the impact of a Covid-19 pneumonia on maternal lung function; in one case, this
368 necessitated preterm delivery at 33 weeks. Covid-19 disease in the mother can pose a
369 maternal-fetal dilemma, because an intervention that would benefit her (i.e. delivery to
370 improve maternal lung function) might result in morbidity or mortality to the neonate if
371 delivered prematurely. The rate of medically-indicated preterm birth is a critically
372 important feature contributing to the vulnerability of pregnant women to Covid-19.

373

374 The impact of Covid-19 on resource utilization across all sites was significant and not
375 captured by this data. Outpatient adjustments included changes such as daily symptom
376 screening, daily calls to patients with Covid-19, notification of new visitation policies,
377 rescheduling of appointments and conversion to new telemedicine platforms. In the
378 hospital, limitations on the number of people providing labor support, development of new
379 practices for universal screening before/upon admission, new construction of negative
380 pressure rooms and frequent care coordination between obstetrics and intensive care
381 unit teams. All of these changes resulted in increases in time, supplies and staffing that
382 created challenges to delivery of the usual standard of maternity care. Further, the impact
383 of quarantine on women's lives, stress, mental health, bonding, breastfeeding and child
384 development are critically important outcomes not captured in our case series.

385

386 *Research Implications*

387 Rigorous population-based studies are needed to identify risk factors for severe disease,
388 the rate of adverse outcomes in pregnancy and to ascertain whether risks are increased
389 in late pregnancy similar to influenza(41-43). Whether vertical transmission occurs
390 remains unknown, but several case reports appear suspicious (16-18). We must also
391 conduct follow-up studies of children exposed to SARS-CoV-2 infections in pregnancy to
392 determine the risk for Covid-19 disease in the immediate newborn period. Both preterm
393 birth and maternal infections may pose short- and long-term risks for the child including
394 mortality, prematurity-related complications, and neuropsychiatric disease as an adult(19,
395 20, 44, 45). Finally, we must determine the impact of quarantine and mother-newborn
396 separation on maternal health so that we can better support women in the postpartum
397 period.

398

399 None of the pregnant women in our case series, who received medications for Covid-19
400 (e.g. remdesivir), were enrolled in a clinical trial, despite recommendations from the
401 Infectious Disease Society of America that treatment of hospitalized patients with Covid-
402 19 occur in the context of a clinical trial (46). Pregnant and breastfeeding individuals are
403 almost universally excluded from Covid-19 clinical treatment trials, including the World
404 Health Organization sponsored SOLIDARITY trial (ISRCTN83971151) (47). Currently,
405 pregnant women can access both remdesivir through compassionate use and
406 convalescent plasma (NCT04338360) through an expanded access clinical trial if they
407 have confirmed severe Covid-19 (46, 48). In general, trials that allow inclusion of pregnant

408 and breastfeeding women focus on outpatient treatment trials (NCT04354428,
409 NCT043558068) or post-exposure prophylaxis trials (NCT04308668, NCT04328961),
410 with the exception of a convalescent plasma trial for patients hospitalized for Covid-19
411 (NCT04348656). It is imperative to enroll pregnant women in clinical trials testing Covid-
412 19 therapeutics to enable development of evidence-based treatment guidelines.

413

414 *Strengths and Limitations*

415 The study's main strength is the inclusion of multiple health systems across Washington
416 State representing counties with the highest burden of Covid-19 and approximately 40%
417 of annual deliveries in the state. We also included both symptomatic and asymptomatic
418 cases, as well as infections from all trimesters, allowing us to better describe the full range
419 of infection in pregnancy. Lastly, all data were initially abstracted and/or reviewed for
420 accuracy by clinical obstetric providers. An important study limitation is that some cases
421 could have been missed despite the use of multiple methods of case detection at most
422 sites. It is also likely that our case series underestimates the prevalence of asymptomatic
423 cases, as testing resources were primarily directed towards symptomatic cases during
424 this study period. This would bias our study towards inclusion of patients with worse
425 clinical outcomes. Finally, other studies appear to have found more severe respiratory
426 complications when infection occurred during the peripartum period, which was not well
427 captured in our study as delivery outcomes were only available in eight women (6, 25, 49,
428 50).

429

430 *Conclusions*

431 In this population-based case series from Washington State, 15% of pregnant patients
432 with Covid-19 were hospitalized with severe disease. Nearly all women were overweight
433 or obese prior to pregnancy and had other important co-morbidities, such as asthma and
434 hypertension. Our data suggests that pregnant women who have common health
435 conditions like obesity and asthma, may be at a greater risk for severe Covid-19 disease
436 and medically-indicated preterm delivery to improve lung function. Larger population-
437 based studies are needed to determine whether pregnant individuals are at higher risk
438 for severe Covid-19 illness compared to non-pregnant adult women, and to what extent
439 obesity and other co-morbidities may enhance risk (51). Taken together, pregnant women
440 should be considered a high risk population for severe Covid-19 disease, particularly for
441 women in the second and third trimesters that began pregnancy overweight or obese.

442

443 ACKNOWLEDGMENTS

444 We would like to acknowledge several individuals for their support of this project. We
445 thank Ms. Adrienne Meyer and Dr. Emily Guthrie with the University of Washington IRB
446 for organizing reliance agreements with multiple study sites. Ms. Emily Begnel graciously
447 volunteered her time to help build the REDCap database. We are thankful for the
448 assistance provided by Ms. Bethann M. Pflugeisen for implementing site-specific
449 algorithms to identify pregnant patients with Covid-19 in the Multicare Health system. Ms.
450 Nicole Wothe provided administrative assistance with project management and
451 manuscript submission. We thank Dr. Benjamin T. Bradley for providing advice
452 associated with the fetal autopsy.

589 **Table 1. Demographics, Co-morbidities, and Pregnancy History for 46 Pregnant**
 590 **Patients with SARS-CoV-2 Infections**
 591

Characteristic	Patients (N=46)*
Demographics	
Age	29 (26-34)
Race	
Asian	2 (4.3)
Native Hawaiian or Other Pacific Islander	1 (2.2)
Black or African American	3 (6.5)
White	28 (60.9)
Multiracial	1 (2.2)
Other	2 (4.3)
Unknown / Not Reported	9 (19.6)
Ethnicity	
Hispanic or Latino	11 (23.9)
Not Hispanic or Latino	33 (71.7)
Unknown / Not Reported	2 (4.3)
Type of Insurance at diagnosis	
Public	18 (39.1)
Private	27 (58.7)
Unknown	1 (2.2)
Pre-pregnancy Existing Co-Morbidities	

Type 2 diabetes	3 (6.5)
Asthma	4 (8.7)
Hypothyroidism	3 (6.5)
Hypertension	2 (4.3)
Other co-morbidities [†]	5 (10.9)
Pre-pregnancy BMI[‡]	
Underweight (<18.5)	1 (2.4)
Normal (18.5-24.9)	14 (33.3)
Overweight (25.0-29.9)	12 (28.6)
Obese (≥30.0)	15 (35.7)
Pregnancy History	
Gravidity	2.0 (2.0-5.0)
Parity	1.0 (0.0-2.0)
History of preterm birth	3 (6.5%)

592

* Characteristics summarized as n(%) or median(IQR).

† Other comorbidities included Crohn's disease with immunosuppressive therapy (n=1); heart valve repair (n=1); Papillary thyroid carcinoma w/ thyroidectomy (n=1); seizure disorder (n=2)

‡ Only available for 42 patients. Pre-pregnancy weight or weight prior to 12 weeks gestational age was used if pre-pregnancy weight not available. For one patient, their 14 weeks of gestation weight was used to calculate pre-pregnancy BMI.

593 **TABLE 2. Covid-19 Symptoms at First Positive SARS-CoV-2 Test**

Characteristic	Patients (N=46)*
Symptomatic prior to (or at) first positive test	43 (93.5%)
Among Symptomatic (n=43):	
Gestational age at symptom onset (weeks)	27.0 (21.0-33.9)
Number of symptoms reported	2 (1-5)
Reported Symptoms [†] :	
Cough	30 (69.8%)
Subjective fever or chill	22 (51.2%)
Nasal congestion	21 (48.8%)
Shortness of breath/dyspnea	19 (44.2%)
Headache	14 (32.6%)
Loss of taste or smell	13 (30.2%)
Myalgia	13 (30.2%)
Fatigue	12 (27.9%)
Sore throat	12 (27.9%)
Other symptom [‡]	10 (23.3%)
Nausea or Vomiting	5 (11.6%)
Diarrhea	3 (7.0%)
Days between symptom onset to resolution [§]	24 (13, 37)

594

* Characteristics summarized as n (%) or median (IQR).

† No significant difference ($p < 0.05$) by trimester of infection for any reported symptom. One patient was missing symptom data for the day of positive testing, but symptom data were available and included for a subsequent Covid-19 associated encounter.

‡ Chest pain or tightness n=5, dizziness n=1, night sweats n=1, tachycardia n=1, epigastric pain n=1, right upper quadrant pain n=1

§ Estimated by generating a Kaplan-Meier curve to incorporate censoring.

Highest Creatinine (mg/dL)	0.51	0.47	0.66	0.6	0.77	0.51	

595

Pregnant patients with severe Covid-19 disease were non-Hispanic white (n=4), Hispanic race unknown (n=1), and race/ethnicity unknown (n=1).

Abbreviations: AST: aspartate transaminase; ALT: alanine aminotransferase; CXR: Chest X-ray; GA: gestational age; CS: cesarean section; ICU: intensive care unit; RR: respiratory rate; WBC: white blood cells

*Age group (5 year increments) is presented to make it less likely that a patient might be identifiable.

† Pre-pregnancy BMI not available. This value represents BMI at SARS-CoV-2 diagnosis, which was at 14 weeks gestation.

‡ This patient had three emergency department visits for respiratory concerns, one of which prompted this hospitalization.

596 **Table 4. Maternal, Pregnancy, and Neonatal Outcomes for Eight Deliveries Among**
 597 **SARS-CoV-2 Infected Pregnant Patients**

598

Characteristics	Deliveries (N=8)*
Delivery Characteristics	
Gestational age at delivery	38.4 (37.5-39.8)
Preterm Birth	1 (12.5)
Labor	
None	2 (25.0)
Spontaneous [†]	2 (25.0)
Induced [‡]	4 (50.0)
Outcome	
Live birth	7 (87.5)
Stillbirth	1 (12.5)
Delivery Route	
Vaginal	5 (62.5)
Cesarean [§]	3 (37.5)
Complications	
<i>Pregnancy</i>	
Gestational diabetes ^{**}	1 (12.5)
Gestational hypertension ^{††}	2 (25.0)
Cholestasis	1 (12.5)

Delivery

Placental abruption 1 (12.5)

Non-reassuring fetal status / fetal distress 3 (37.5)

Postpartum

Postpartum preeclampsia with severe features^{‡‡} 2 (25.0)

SARS-CoV-2 testing

Days between positive test and delivery 7.5 (5.0-11.5)

599

* Characteristics summarized as n(%) or median(IQR).

† One patient with spontaneous onset of labor had labor subsequently augmented.

‡ Reasons for inductions included fetal demise n=1, premature rupture of membranes n=1, diabetes n=1, hypertensive disorders of pregnancy n=1, growth restrictions n=1, scheduled induction n=2. No inductions of labor were performed to improve maternal lung function.

§ Cesarean section indications included (multiple indications in some cases): repeat cesarean delivery n=2, non-reassuring fetal status=1, diabetes n=1, respiratory compromise n=1, second stage arrest n=1, malpresentation n=1, Covid-19 n=2 (decision in the context of Covid-19 and other co-morbidities n=1, worsening respiratory status n=1), other n=1 (cholestasis, history of shoulder dystocia, fetal macrosomia this pregnancy)

** Treated with insulin.

†† Diagnosed concurrently with (n=1) or after positive SARS-CoV-2 test (n=1)

‡‡ Both cases were defined as severe by blood pressure criteria.

600 **FIGURE LEGENDS**

601 **Figure 1.** Timeline of Symptom Onset and Resolution, Laboratory Testing, Covid-19
602 Hospital Admission and Delivery for 46 Pregnant Patients. Time is shown on the x-axis
603 and is measured by gestational age in weeks. Each line of the y-axis reflects an individual
604 patient. Gestational age of first positive SARS-CoV-2 test (red star), length of symptoms
605 (black lines; gestational age at symptom onset marked by black dot, gestational age/days
606 postpartum at symptom resolution marked by black dot if resolved and a black arrow if
607 ongoing at last encounter (censoring), length of Covid-19 hospitalizations (grey bar), and
608 gestational age at delivery (blue vertical line) are shown for each patient, as applicable.
609 Three patients were asymptomatic. Of the seven patients hospitalized for Covid-19
610 associated respiratory concerns, six were severe (Table 3).
